### ABSTRACT:

In the modern era, image captioning has become one of the most widely required tools. Moreover, there are inbuilt applications that generate and provide a caption for a certain image, all these things are done with the help of deep neural network models. The process of generating a description of an image is called image captioning. It requires recognizing the important objects, their attributes, and the relationships among the objects in an image. It generates syntactically and semantically correct sentences. In this paper, we present a deep learning model to describe images and generate captions using computer vision and machine translation. This paper aims to detect different objects found in an image, recognize the relationships between those objects and generate captions. The dataset used is Flickr8k and the programming language used was Python3, and an ML technique called Transfer Learning will be implemented with the help of the Xception model, to demonstrate the proposed experiment. This paper will also elaborate on the functions and structure of the various Neural networks involved. Generating image captions is an important aspect of Computer Vision and Natural language processing. Image caption generators can find applications in Image segmentation as used by Facebook and Google Photos, and even more so, its use can be extended to video frames. They will easily automate the job of a person who has to interpret images. Not to mention it has immense scope in helping visually impaired people.

### I. INTRODUCTION

Making a computer system detect objects and describe them using natural language processing (NLP) in an age-old problem of Artificial Intelligence. This was considered an impossible task by computer vision researchers till now. With the growing advancements in Deep learning techniques, availability of vast datasets, and computational power, models are often built which will generate captions for an

image. Image caption generation is a task that involves image processing and natural language processing concepts to recognize the context of an image and describe them in a natural language like English or any other language. While human beings are able to do it easily, it takes a strong algorithm and a lot of computational power for a computer system to do so. Many attempts have been made to simplify this problem and break it down into various simpler problems

images as two-dimensional arrays and mapping is done from images to

Figure 1: Our model is based on a deep learning neural network that consists of a vision CNN followed by a language generating RNN. It generates complete sentences as an output

captions or descriptive sentences. In recent years a lot of attention has been drawn towards the task of automatically generating captions for images. However, while new datasets often spur considerable innovation, benchmark datasets also require fast, accurate, and competitive evaluation metrics to encourage rapid progress. Being able to automatically describe the content of a picture using properly formed English sentences may be a very challenging task, but it could have an excellent impact, as an example by helping visually impaired people better understand the content of images online. This task is significantly harder, for instance than the well-studied image classification or visual perception tasks, which are a main focus within the computer vision community. Deep learning methods have demonstrated advanced results on caption generation problems. What is most impressive about these methods is that one end-to-end model is

often defined to predict a caption, given a photograph, rather than requiring sophisticated data preparation or a pipeline of specifically designed models. Deep learning has attracted a lot of attention because it's particularly good at a kind of learning that has the potential to be very useful for real-world applications. The ability to find out from unlabeled or unstructured data is a huge benefit for those curious about real-world applications. [1 - 4]

**II. PROBLEM STATEMENT** The main problem in the development of image description started with object detection using static object class libraries in the image and modelled using statistical language models. [5]

A. Making use of CNN: It's a Deep Learning algorithm that will intake in a 2D matrix input image, assign importance (learnable weights and biases) to different aspects/objects in the image, and be intelligent enough to be able to differentiate one from the other.

B. This model was advantageous in naming the objects in an image but it could not tell us the relationship among them (that's plain image classification).

C. In this paper, we present a generative model built on a deep recurrent architecture that unites recent advances in computer

vision and machine translation and that can effectively generate meaningful sentences.

D. Making use of an RNN: They are networks with loops in them, allowing information to persist. LSTMs are a particular kind of RNN, capable of learning long-term dependencies. [5]

### III. PROPOSED METHODOLOGY

**A. Task** The task is to build a system that will take an image input in the form of a dimensional array and generate an output consisting of a sentence that describes the image and is syntactically and grammatically correct.

**B. Corpus** We have used the Flickr 8K dataset as the corpus. The dataset consists of 8000 images and for every image, there are 5 captions. The 5 captions for a single image helps in understanding all the various possible scenarios. The dataset has a predefined training dataset Flickr\_8k.trainImages.txt (6,000images), development dataset Flickr\_8k.devImages.txt (1,000 images), and test dataset Flickr\_8k.testImages.txt (1,000 images). The Images are opted from six varied Flickr groups and do not contain any well-known personality or places. However, they are manually selected to show a variety of scenes.[1] These datasets(Size 1GB) can be directly

downloaded from the given links(Thanks to Jason Brownlee ):

Figure 3: Glimpse of Flickr8k Text File

**C. PREPROCESSING** Data preprocessing is done in two parts, the images and the corresponding captions are cleaned and pre-processed separately. Image preprocessing is done by feeding the input data to the Xception application of the Keras API running on top of TensorFlow. Xception is pre-trained on ImageNet. This helped us train the images faster with the help of Transfer learning. The descriptions are cleaned using the tokenizer class in Keras, this will vectorize the text corpus and is stored in a separate dictionary. Then each word of the vocabulary is mapped with a unique index value.

**D. MODEL DEEP LEARNING** carries out the machine learning process using an artificial neural network that is composed of several levels arranged in a hierarchy. The model is based on deep networks where the flow of information starts from the

initial level, where the model learns something simple and then the output of which is passed to layer two of the network and input is combined into something that is a bit more complex and passes it on to the third level. This process continues as each level in the network produces something more complex from the input it received from the ascendant level.

## CONVOLUTIONAL NEURAL NETWORKS (CNN)

Convolutional Neural networks are specialized deep neural networks that can process the data that has input shape like a 2D matrix. Images can be easily represented as a 2D matrix. CNN is crucial in working with images. It takes as input an image, assigns importance (weights and biases) to various aspects/objects in the image, and differentiates one from the other. The CNN makes use of filters(also known as Kernels) which help in feature learning(detect abstract concepts, like Blurring, Edge Detection, Sharpening, etc), much the same as a human brain identifying objects in time and space. The architecture performs a better fitting to the image dataset due to the reduction in the number of parameters involved(from 2048 to 256) and the reusability of weights.

Figure 4: Architecture of Convolutional Neural Networks for object classification.[11]

## RECURRENT NEURAL NETWORKS

(RNN) The human brain is evolved in such a way so as to make sense of previous words, and keeping these in mind generate the next words, thus forming a perfect sentence. Basic Neural networks don't have the ability to do this. However, advancements in Recurrent neural networks address this issue. They are networks with loops in them, allowing information to persist for a while, by making use of their internal states, thus creating a feedback loop. [6]

Figure 5: Loop in RNN[6]

Long Short Term Memory networks – usually just called “LSTMs” – are a special kind of RNN, capable of learning long-term dependencies. Remembering information for long periods is practically their default behaviour, and this behaviour is controlled with the help of “gates”. While RNNs

process single data points, LSTMs can process entire sequences. Not only that, they can learn which point in the data holds importance, and which can be thrown away. Hence, the only relevant information is passed on to the next layer. The 3 main gates involved are: input gate, output gate and forget gate. These gates decide whether to forget the current cell value, read a value into the cell, or output the cell value. The hidden states play an important role since the previous hidden states are passed to the next step of the sequence. The hidden state acts as the neural network's memory, as it is storing the data that the neural network has seen before. Thus it allows the neural network to function like a human brain trying to form sentences. [6, 7]

Figure 6: The recurrent module in LSTM contains four interconnected layers.[7]

**ARCHITECTURE** We utilize a CNN + LSTM to take an image as input and output a caption. An “encoder” RNN maps the source sentence (which is of variable length) and transforms it into a fixed-length vector representation, which in turn is used as the initial hidden state of a “decoder”

RNN which ultimately generates the final meaningful sentence as a prediction. [7]

Figure 7: CNN-LSTM structure.[5]

However, we are going to replace this RNN with a deep CNN - since it can produce a rich representation of the input image by embedding it to a fixed-length vector - by first pre-training it for an image classification task and using the last hidden layer as an input to the RNN decoder that generates sentences. [5 - 7]

**IV. EVALUATION.** Execution of the entire program takes place in 5 major steps. The implementation of the five major modules is as follows: A. Data Cleaning and Preprocessing: 1. For a comfortable and fast work experience, we use Google Colaboratory: a tool which provides free GPU/TPU processing power, over our local machines, which can take several hours to do the task that a GPU will take few minutes to do.

2. Our program starts with loading both, the text file, and the image file into separate variables; the test file is stored in a string.

3. This string is used and manipulated in such a way so as to create a dictionary that maps each image with a list of 5 descriptions.

4. The main task of data cleaning involves removing punctuation marks, converting the whole text to lowercase, removing stop words and removing words that contain numbers.

5. Further, a vocabulary of all unique words from all the descriptions is created, which in the future will be used to generate captions to test images.

6. Another aspect of Preprocessing the data involves tokenizing our vocabulary with a unique index value. This is because a computer won't understand regular English words, hence they need to be represented using numbers. The tokens are then stored in a pickle file. i.e. in the form of character stream, but with all the information necessary to reconstruct it into the original object type.

7. The above two preprocessing tasks can be achieved manually or by using the Keras.preprocessing module for ease of writing the code.

8. We proceed to append the <start> and <end> identifier for each caption since these will act as indicators for our LSTM to understand where a caption is starting and where it's ending.

9. We will proceed with calculating the number of words in our vocabulary and finding the maximum length of the description, which will be used in later phases.

## B. Extraction of feature vectors:

1. A feature vector(or simply feature) is a numerical value in the matrix form, containing information about an object's important characteristics, eg. intensity value of each pixel of the image in our case. These vectors, we'll ultimately store in a pickle file.

2. In our model we'll be using Transfer Learning, which simply means, using a pretrained model( in our case the Xception model) to extract features from it.

3. The Xception model is a Convolutional Neural Network that is 71 layers deep. It is trained on the famous Imagenet dataset

which has millions of images and over 1000 different classes to classify from.

4. Python makes using this model in our code extremely easy with `keras.applications.xceptionmodule`. To use it in our code, we'll drop the classification layer from it, and hence obtain the 2048 feature vector.

5. Hence weights will be downloaded for each image, and then image names will be mapped with their respective feature array.

6. This process can take a few hours depending on your processor.

**CONCLUSION** Based on the results obtained we can see that the deep learning methodology used here bore successful results. The CNN and the LSTM worked together in proper synchronization, they were able to find the relation between objects in images. To compare the accuracy of the predicted caption, we can compare them with target captions in our Flickr8k test dataset, using BLEU(Bilingual Evaluation Understudy) score [5, 8]. BLEU scores are used in text translation for evaluating translated text against one or more reference translations. Over the years several other neural network technologies have been used to create hybrid image caption generators, similar to the one proposed here. eg VGG16 model instead of the Xception model, or the GRU model

instead of the STM model. Furthermore, BLEU Score can be used to draw comparisons between these models, to see which one provides maximum accuracy. This paper introduced us to various new developments in the field of machine learning and AI, and how vast this field is. In Fact several topics within this paper are open to further research and development, while this paper itself tries to cover the basic essentials needed to create an image caption generator.
